Executive Summary

Newly released U.S. Environmental Protection Agency (EPA) information on toxic air emissions shows that electric utilities were the biggest air polluters in the U.S. in 2000. The 2000 Toxics Release Inventory (TRI) data constitute our nation's premier database of information on how much toxic air, water, and land pollution is released each year by various industries. Coal- and oil-fired electric power plants first reported to TRI for 1998. The latest data also contain new information on persistent, bioaccumulative toxic chemicals, or PBTs.

This report is the first in-depth analysis of the quantity and nature of coal- and oil-burning power plant toxic pollution brought to light in the 2000 TRI data. It demonstrates that electric utility emissions can and do in fact present serious public health concerns. It also shows that special pollution exemptions for power plants contribute to the massive quantity of toxic materials released by the electric power industry each year.

EPA had previously estimated overall electric utility mercury air emissions, but had not had a plant-by-plant accounting of mercury releases submitted by power plants until the 2000 TRI data. These data confirm that coal-fired power plants continue to be the largest industrial source of mercury air emissions in the United States. The new TRI data also show that electric utilities are the second largest industrial source of airborne dioxin and dioxin-like compounds. Mercury is known to affect the development of a child's brain and nervous system, and dioxin is known to cause cancer in humans at very low doses. They are also endocrine disruptors, chemicals that can cause trans-generational effects in extremely small doses because they mimic human hormones.

In 2000, EPA determined that power plant mercury emissions threaten public health, and decided to begin the process of regulating mercury air emissions from power plants. At the same time, EPA announced that it would also review other toxic chemical emissions from power plants to determine if they require regulation. Utilities claim that their toxic releases – while large in the aggregate – pose no threat to human health or the environment. However, neither the electric utility industry nor EPA has examined potential long-term risk to children, the elderly, and people with respiratory illnesses. In addition, the effects of exposure to multiple pollutants at the same time have not been evaluated. Both EPA and the electric utilities have also failed to analyze how power plant toxic chemical emissions help form fine particle pollution, an enormous public health concern.

Key Findings

- Electric utilities released nearly **1.1 billion pounds of toxic pollution** in 2000, more than any other industry in the U.S. except for metal mining, which releases most of its toxics to land. Electric utilities emit more toxic chemical air pollution than the chemical, paper, and primary metals industries *combined*.
- Electric utilities accounted for **41 percent of all TRI air emissions** in 2000, releasing **more than three-quarters of a billion pounds** in air pollutants.
- **Southern Company, American Electric Power (AEP), Progress Energy** (holding company for Florida Power and CP&L), and **Tennessee Valley Authority (TVA)** ranked highest for toxic air emissions in 2000. Southern Company was responsible for nearly 12 percent of reported TRI air emissions from the entire electric utility industry. Southern, AEP, and TVA also ranked first, second, and third for total toxic releases to air, water, and land.
- **Ohio, North Carolina, Pennsylvania, West Virginia, and Florida** were the top five states for electric utility toxic air emissions in 2000. Together, power plants in these five states were responsible for 44 percent of US electric utility toxic air emissions.
- Coal- and oil-fired power plants released over **108,000 pounds of persistent, bioaccumulative, toxic (PBT) chemicals to the air in 2000**. EPA lowered the reporting thresholds for these chemicals because they remain in the environment for long periods of time and accumulate in body tissue, greatly increasing the likelihood and amount of exposure. The 2000 TRI data represent the first full accounting of releases of chemicals such as mercury and PCBs. While most of these substances were on the TRI reporting list prior to 2000, the quantities of these materials generated on site were too low to meet the previous TRI threshold.
- Coal-fired power plants released nearly **95,000 pounds of mercury and mercury compounds** into the air in 2000, and were the largest industrial source of mercury emissions. Fifty-eight percent of industrial mercury air emissions came from power plants in 2000. The chemical industry and metal mining ranked second and third for mercury air emissions in 2000.¹
- **American Electric Power, Southern Company, Reliant Energy, Dominion Resources, and Tennessee Valley Authority** were the five electric utility parent companies with the greatest air emissions of mercury in 2000. These five companies accounted for nearly one-third of all US electric utility mercury air emissions, and AEP alone released 10 percent of US power plant mercury air emissions.

¹ Note that municipal waste incinerators, a significant source of airborne mercury, do not report to TRI.

- **Texas, Ohio, Pennsylvania, Indiana, and West Virginia** were the five states with the greatest electric utility mercury air emissions in 2000, accounting for 39 percent of power plant mercury air emissions. Power plants in Texas alone accounted for nearly 10 percent of nationwide power plant mercury air emissions.
- The 2000 TRI required facilities to report emissions of dioxin and dioxin-like compounds for the first time. **Electric utilities released over 700 grams of extremely toxic dioxin and dioxin-like compounds into the air** in 2000. The industry appears to have reported the second largest amount of air emissions of dioxin and dioxin-like compounds in 2000, accounting for 23 percent of dioxin air emissions from industrial sources reporting to TRI.²
- **Cogenetrix Energy** (with power plants in 12 states, mostly on the east coast) was the single largest source of electric utility dioxin air emissions, releasing more than three times as much dioxin and dioxin-like compounds as the electric utility parent company with the next highest releases. Other companies in the top five for dioxin air emissions in 2000 were **Tennessee Valley Authority, XCEL Energy** (with power plants in 12 states, mostly western), **PPL, Constellation Energy Group** (Maryland), and **Transalta Centralia Generation**.
- **Virginia, Florida, Wisconsin, North Carolina, and Pennsylvania** were the top five states for air emissions of dioxin and dioxin-like compounds in 2000. Virginia accounted for nearly 12 percent of the electric utility's air emissions of dioxin and dioxin-like compounds.
- Coal- and oil-fired power plants released over **10 million pounds of toxic metals and metal compounds** to the air in 1998, many of which are known or suspected carcinogens and neurotoxins. Power plants have no required controls specifically for toxic metals, even though they are among the largest sources of such pollution, releasing metals both to air and to land.
- Coal- and oil-fired power plants released over **three-quarters of a billion pounds of dangerous acid gases** to the environment in 2000, constituting the vast majority of their toxic pollution. Acid gases can cause acute respiratory problems, and aggravate asthma and emphysema. They also contribute to the

² This analysis includes one chemical industry facility, Solutia in Decatur, AL, that reported the largest dioxin air emissions of any facility in the country, 807.39 grams. EPA has contacted the facility to verify the data and has chosen to include Solutia's emissions in the total. This makes the chemical industry number one for air emissions of dioxin and dioxin-like compounds. If Solutia's data are excluded, electric utilities would be number one.

Also note that municipal waste incinerators do not report to TRI. EPA has previously estimated that municipal waste incinerators are a significant source of dioxin air emissions, and may exceed dioxin air emissions by electric utilities. See EPA's *Inventory of Sources of Dioxin in the United States*. EPA/600/P-98/002Aa, April 1998.

formation of fine particle pollution, which is linked to as many as 30,000 premature deaths each year from the power sector alone.³

- While, on average, other industries reporting to TRI release about 15 percent of their toxic chemical waste to the environment, coal- and oil-burning **power plants release 66 percent of their waste to the environment** because most power plants are not required to control their emissions.

Recommendations

The TRI data reveal that the electric power industry is by far the largest aggregate source of some of our most harmful toxic air pollution, especially acid gases and mercury, and is the second largest source of airborne dioxin. Reducing this enormous source of toxic pollution will require a combination of closing special loopholes that exempt electric utilities from pollution controls that apply to other industries, modernizing our current fleet of power plants, and investing in cleaner power sources. Some of the measures that should be taken immediately are:

- EPA is in the midst of setting mercury emission standards for coal-fired power plants, and may include other toxic chemicals. The Agency must propose standards by the end of 2003 for finalization by the end of 2004, and power plants must comply by 2007. At present, it is unclear if EPA also plans to regulate other toxic emissions besides mercury. This analysis confirms that EPA needs to strictly regulate *all* electric utility toxic air emissions – especially dioxin, acid gases, and metals -- so that, at a minimum, power plants meet the same standards other industries meet for toxic air pollution.
- EPA is currently finalizing Best Available Retrofit Technology (BART) standards for “grandfathered” power plants that were built between 1962 and 1977 and are exempt from meeting emissions standards. Stringent new BART rules would dramatically reduce fine particle regional haze by requiring power plants to install sulfur scrubbers, selective catalytic reduction (SCR) equipment and other cost-effective cleanup technologies. The combined effect of these controls would be dramatic reductions in power plant toxic air emissions. EPA should move forward quickly with stringent BART cleanup rules.
- EPA should redouble its efforts to vigorously enforce the Clean Air Act’s New Source Review (NSR) provisions, requiring electric utilities to install emission controls if they make major modifications to power plants. Full enforcement of NSR will lead to dramatic reductions in power plant emissions. In a manner similar to the BART rules, NSR enforcement will result in the installation of modern pollution control technology that will substantially reduce air toxic emissions, since sulfur and nitrogen control technologies remove other power plant toxic emissions as a co-benefit.
- Congress is currently considering proposals that would take a comprehensive approach to cleaning up power plants (rather than regulating pollutant by pollutant), enabling the industry to make more rational decisions on how best to meet their environmental obligations.¹ These proposals include provisions

¹ National Environmental Trust, *Cleaning up Air Pollution from America’s Power Plants: The Facts*. April 2002.

to close an existing loophole that allows older power plants to escape emissions controls for sulfur dioxide and nitrogen oxides. Reducing emissions of pollutants such as sulfur dioxide, nitrogen oxides, carbon dioxide and mercury will also help reduce other toxic air pollution. For example, sulfur dioxide controls are extremely effective at reducing emissions of acid gasses, the largest releases from electric power plants.

- The vast majority of electric power plants operating today are more than 30 years old. They burn coal and oil to produce electricity, both of which contain relatively high levels of impurities that result in toxic air pollution. Modernizing this fleet of plants by converting or replacing them with cleaner alternatives such as natural gas-fired power plants will help reduce toxic air pollution from electric utilities.
- Finally, a great deal of toxic air pollution can be avoided by shifting some of our electricity needs to renewable power sources such as wind, geothermal, solar and biomass. Energy efficiency measures will also reduce toxic air pollution by reducing the amount of fossil fuel burned to generate electricity.

The time has come for electric utilities to do their fair share to reduce the threats that toxic pollutants pose to our families, our future, and our environment. The time is long past due for power plants to stop emitting more toxic air pollution than the chemical, paper, and primary metals industries *combined*.

Introduction

1998 marked the first year that electric utilities were required to report to U.S. EPA's Toxics Release Inventory, or TRI. Since 1987 industrial facilities engaged in manufacturing have been required to report to TRI their annual releases to the environment and off-site transfers of waste on a chemical-specific basis. Since the first reports, TRI has been expanded to include more activities, industries, and substances. In 1991, TRI was expanded to require data on pounds of on-site recycling, energy recovery, and treatment activities at facilities. In 1995, the number of substances reportable to TRI nearly doubled. In 1997, EPA expanded the types of facilities required to report to TRI to include electric utilities burning coal or fuel oil, among other new sources such as mining. Finally, in 1999, EPA set lower reporting thresholds for persistent, bioaccumulative, toxic (PBT) chemicals, greatly expanding data collected on substances of concern.

Although it is a reporting program and does not set emission limits, TRI has been responsible for huge reductions in emissions from industrial facilities. Simply having to report the data and subsequently having those data made public has caused facilities to examine their processes and reduce releases to the environment.² From 1988, the year EPA uses as its TRI baseline, reported releases to air, water, and land, and injections into deep wells have decreased by nearly 50 percent among the manufacturing sector facilities that report to TRI.³ For many companies, assembling their 1987 TRI numbers was a big surprise – they had never examined their emissions as a whole, and the totals were extremely high. And, of course, the numbers were a surprise to communities and citizens' groups that had never previously had access to the information.

The numbers have turned out to be no less surprising for the 704 coal- and oil-burning electric power plants reporting to TRI for 2000. ***Nationwide, electric utilities ranked number one for air emissions in the TRI data, and number two for total TRI releases in 2000.***

Even before the TRI toxic air pollution data became available, electric power plants were known to be the largest industrial source of air pollutants such as smog-forming nitrogen oxides, soot-forming sulfur dioxide, and carbon dioxide, a powerful greenhouse gas.⁴ The vast majority of this pollution comes from older coal-fired

² For an analysis of TRI's impact on emissions reduction, see A. Fung and D. O'Rourke, "Reinventing Environmental Regulation from the Grassroots Up: Explaining and Expanding the Success of the Toxics Release Inventory." *Environmental Management.*, Vol. 25, No. 2, pp. 115-127 (2000)

³ This figure includes only facilities in the manufacturing sector, and includes only the core set of chemicals that has been reported continuously since 1988. It does not include the electric power industry.

⁴ Nationally, annual power plant emissions are responsible for 36 percent of carbon dioxide (2 billion tons), 64 percent of sulfur dioxide (13 million tons), 26 percent of nitrogen oxides (6 million tons) and

power plants.⁵ The TRI data now confirm that these power plants are not only the largest industrial source of conventional air pollutants, but that they are also by far the largest source of our most toxic air pollutants, such as mercury, as well as acid gases and toxic metals, and are the second largest source of airborne dioxin.

This report examines nationwide and state TRI electric utility data for 2000. It shows the quantity and nature of toxic pollutants reported by power plants. It also suggests ways in which the massive amount of toxic power plant pollution can be reduced. The numerous data tables at the end of the report reveal how much toxic pollution electric utilities emit compared to other industries, rank the top-polluting utility holding companies, and list by amount the more than 70 toxic chemicals released by power plants to the environment. The data tables also contain state-by-state information on electric utility toxic releases, including the quantity of toxic pollution released by each power plant in all 50 states.

52 tons of mercury (note that this is not the mercury data submitted to TRI, but an EPA estimate from other sources). US EPA, *National Air Quality and Emission Trends Report, 1997* (December 1998), Tables A-4 and A-8, pp. 114, 117. Available online at <http://www.epa.gov/oar>.

⁵ Among power plants, older coal-fired facilities produce the most pollution. Fifty-six percent of power plant boilers in operation in the U.S. are fueled by coal. However, they account for over 93 percent of nitrogen oxides, over 96 percent of sulfur dioxide, over 88 percent of carbon dioxide, and 99 percent of mercury emissions for the entire electric industry. US EPA, Acid Rain Program, *National Summary Percent Contribution by Unit Fuel Type*. Available online at http://www.epa.gov/acidrain/emissions/us_sum.htm.

National TRI Data on Electric Power Plants

How much toxic air pollution did electric utilities report for 2000?

Electric utilities reported releasing over **787 million pounds** of chemicals to the air in 2000, and reported **nearly 1.1 billion pounds** of total releases to air, water, and land (see **Table 1**). Nationally, electric utilities ranked number one for industrial toxic air emissions in 1998, and number two for total TRI toxic releases, behind the metal mining industry.⁶

What are the top electric utilities or utility holding companies for TRI releases?

Southern Company, American Electric Power (AEP), Progress Energy (holding company for Florida Power and CP&L) **and Tennessee Valley Authority (TVA)** ranked highest for TRI air emissions in 2000 for the utility industry (see **Table 2**). Southern, AEP, and TVA also ranked first, second, and third for total TRI releases. Southern Company reported air emissions of over 92 million pounds of TRI chemicals to the environment in 2000, and was responsible for nearly 12 percent of TRI air emissions from the entire utility industry.⁷

What chemicals did electric utilities report to TRI?

2000 was the first year for reporting many PBT chemicals at lowered thresholds. Data for mercury and dioxin are discussed in greater detail below. The top three chemicals released as reported by electric utilities – **hydrochloric acid, sulfuric acid, and hydrofluoric acid** (also known as hydrogen fluoride), accounted for nearly **98 percent of electric utility TRI air emissions** in 2000 (see **Table 3**). Power plants also reported releasing over **10 million pounds of metals and metal compounds** to the air. The reported metals with the greatest air emissions were compounds of zinc, barium, nickel, selenium, and manganese. This total for metals

⁶ Facilities report their industry to TRI by means of Standard Industrial Classification (SIC) codes. A facility may report more than one SIC code to TRI, although the first SIC code reported is supposed to represent the major activity of the facility. This report uses the primary SIC code as the designation for the entire facility.

⁷ Although power plants report the names of their parent companies to TRI, they do not always report their ultimate parent company, especially when the electric utility that owns the plant is a subsidiary of a holding company. In addition, facilities reporting the same parent companies may use slight variations in name that do not allow the data for a parent company to be easily aggregated (for example, “The Southern Company” as opposed to “Southern Company,” or using initials or abbreviations). Given the lag between data reporting and data availability, these parent company or holding company designations may not represent the current status as to number of plants and total emissions.

includes 144,000 pounds of air emissions of lead and lead compounds, which will have a lower reporting threshold for the 2002 reporting year.⁸

Table 3 lists air emissions, total releases, and production-related waste for TRI chemicals reported by electric utilities. Production-related waste includes releases to land, air, or water, amounts of each chemical managed on site (by recycling, energy recovery, or treatment), plus amounts of each chemical shipped off site as waste. ***Sixty-six percent of production-related waste from power plants ended up as releases to the environment***, indicating little waste management activity, and few power plants with emission controls. In contrast, for non-utilities, only 15 percent of all TRI production-related waste was released to the environment.

Electric utilities released over 108,000 pounds of persistent, bioaccumulative, toxic (PBT) chemicals to air in 2000. Mercury accounted for the vast majority of these emissions, but power plants released other extremely toxic chemicals such as polychlorinated biphenyls (PCBs) and polycyclic aromatic compounds (PACs).⁹

How much mercury did power plants release in 2000?

Electric power plants were the largest source of mercury air emissions in 2000. In total, power plants released nearly 95,000 pounds of mercury as air emissions, more than all other industries combined (see **Table 4**).¹⁰ **American Electric Power, Southern Company, and Reliant Energy** were the parent or holding companies responsible for the greatest mercury air emissions, accounting for nearly one quarter of the industry's mercury air emissions (see **Table 5**).

Why are mercury air emissions important?

Mercury is released to water and to land as well as to air.¹¹ It has been known since the 1950s that releases of mercury from human activity (as opposed to volcanoes, for example) can cause fish and other wildlife to build up mercury levels of concern in body tissue. However, there is a broad scientific consensus that air emissions of

⁸ See the Data and Methodology section for an explanation of lowered TRI reporting thresholds for persistent, bioaccumulative, toxic (PBT) chemicals. Lead and lead compounds will have a threshold of 100 pounds for the 2002 reporting year. It is likely that far many more power plants release lead and lead compounds to the air than reported for 2000, and the lower reporting threshold will provide more data.

⁹ For a discussion of PCBs, mercury, and other endocrine disruptors, see Colburn et. al., *Our Stolen Future: Are We Threatening Our Fertility, Intelligence, and Survival?* New York: Dutton, 1996.

¹⁰ This total includes elemental mercury and mercury contained in compounds. Note also that municipal waste incinerators, a significant source of mercury emissions, do not report to TRI.

¹¹ With the exception of the mining industry (metal and coal) and facilities that manage and dispose of waste, the majority of industrial mercury releases are air emissions.

mercury are responsible contamination of fisheries, which results in human exposure through fish consumption.¹² Mercury is the pollutant most responsible for fish advisories, with advisories in 44 states.

Airborne mercury can travel long distances and deposits primarily via rain in oceans, lakes, and rivers far from where it was emitted. The mercury concentrates in the muscle or tissue of fish – in fact, the concentration of mercury in fish tissue can be tens to thousands of times greater than the concentration of mercury in the water the fish inhabits. Humans and other animals eating the fish are then exposed to a higher dose of mercury, which also accumulates in their tissues as well. While the mercury may or may not harm an adult eating the fish (although this is clearly of greater concern for populations that eat more fish, particularly subsistence populations), bioaccumulation of mercury means that a pregnant woman can pass mercury to her unborn child after consuming fish that contain mercury.

Mercury exists in three forms: elemental mercury, inorganic mercury compounds (primarily mercuric chloride), and organic mercury (primarily methyl mercury). All forms are quite toxic, and each form has different health effects. Exposure to elemental or methyl mercury can result in central nervous system effects, while exposure to inorganic mercury can result in kidney damage. Methyl mercury is the form that is of concern for bioaccumulation in fish and other animal tissue. Exposure to methyl mercury, via eating fish, can cause developmental effects. Children born to women who have high levels of methyl mercury have exhibited mental retardation, blindness, and cerebral palsy, among other birth defects.¹³

How much dioxin did power plants release in 2000?

Electric utilities appear to have been the number two source of air emissions of dioxin and dioxin-like compounds in 2000, releasing over 700 grams (see **Table 6**), more than any other industry reporting to TRI except the chemical industry.¹⁴

¹² U.S. EPA. *Mercury Study: Report to Congress*. Office of Air Planning Quality and Standards and Office of Research and Development. EPA-452/R-97-003.

¹³ For other information on mercury and other PBT chemicals, see *Poisoning Our Future: The Dangerous Legacy of Persistent Toxic Chemicals*. National Environmental Trust and U.S. Public Interest Research Group, November 1998.

¹⁴ The caveat is in place because there is still some uncertainty about the dioxin data reported to TRI. This analysis includes one chemical industry facility, Solutia in Decatur, AL, that reported the largest dioxin air emissions of any facility in the country, 807.39 grams. EPA has contacted the facility to verify the data and has chosen to include Solutia's emissions in the total. This makes the chemical industry number one for air emissions of dioxin and dioxin-like compounds. If Solutia's data are excluded, electric utilities would be number one. It is possible that there are still some incorrect power plant dioxin data, and there may also be incorrect data submitted for facilities in other industries.

Also note that municipal waste incinerators do not report to TRI. EPA has previously estimated that municipal waste incinerators are a significant source of dioxin air emissions, and may exceed dioxin

Cogenetrix Energy (power plants in 12 states, mostly on the east coast), **Tennessee Valley Authority**, and **XCEL Energy** (power plants in 12 states, mostly western) were the top three parent or holding companies for dioxin air emissions. These three companies accounted for nearly 30 percent of electric utility dioxin air emissions in 2000 (see **Table 7**).

What are dioxin and dioxin-like compounds?

Dioxin and dioxin-like compounds are chlorinated chemicals that are byproducts of combustion, such as burning coal in electric power plants, and are not produced intentionally. They cause toxic effects at very low levels compared to other environmental toxins. However, some dioxin-like compounds are more toxic than others. Unfortunately, it is not possible to get a breakdown of the amounts of dioxin and each of the dioxin-like compounds from the TRI data.¹⁵ Thus, this report cannot characterize the relative toxicity of dioxin emissions from the electric power industry compared to other industries.

Like mercury, airborne emissions of dioxin can travel long distances and deposit far from their sources. Dioxin and dioxin-like compounds are extremely stable under most environmental conditions, and persist in the environment for decades.¹⁶ Dioxin and dioxin-like compounds have been found throughout the world in air, soil, water, sediment, fish, shellfish, meat, and dairy products. Dietary intake is thought to be the main pathway of human exposure. Immune system function, learning behavior, and the reproductive system all can be affected by prenatal dioxin exposure. Children and adults exposed to dioxin can also experience immune system impairment and the chemicals may cause certain kinds of cancer. Dioxin and dioxin-like compounds may also be implicated in lowered human and animal fertility.¹⁷

air emissions by electric utilities. See EPA's *Inventory of Sources of Dioxin in the United States*. EPA/600/P-98/002Aa, April 1998.

¹⁵ Facilities report the total amount of releases of dioxin and dioxin-like compounds all together. They may also report the weight fraction of each of the 17 compounds reportable to TRI if they have that information readily available. However, the facility can report the breakout for its largest emission or for total emissions, and it is not possible to determine which one the breakout applies to. Some industry associations have provided blanket estimates of the breakdown for their industries, however, these estimates are not necessarily representative of individual facilities.

¹⁶ Persistence is a measure of how long a chemical remains in the environment and is typically measured by half-life: the amount of time it takes for half of the original amount of a chemical to degrade into another substance. TRI data must be reported at lower thresholds for bioaccumulative chemicals that have half-lives of two months or more.

¹⁷ See *Poisoning Our Future: The Dangerous Legacy of Persistent Toxic Chemicals* (National Environmental Trust and U.S. Public Interest Research Group, November 1998) for a listing of some U.S. EPA publications with information on dioxin and dioxin-like compounds, including health effects information and estimated emissions for various industries.

Are electric power plant emissions dangerous?

EPA stated in 1998 that some power plant emissions were a public health concern and required further study. On December 14, 2000, EPA announced that “mercury emissions from electric utility steam generating units are considered a threat to public health and the environment,” and that the Agency would begin a process of setting a power plant mercury emission standard.¹⁸ The deadline for proposing the standard is December 15, 2003, with a final standard by December 15, 2004. Coal-fired power plants will have to meet the standard by December 15, 2007.

EPA also determined that “arsenic and a few other metals (e.g. chromium, nickel, cadmium) are of potential concern” for causing cancer, and that the risk was not low enough “to eliminate those metals as a potential concern for public health. Dioxins, hydrogen chloride [hydrochloric acid] and hydrogen fluoride [hydrofluoric acid] are three additional [hazardous air pollutants] that are of potential concern and may be evaluated further during the regulatory process. ...Due to data gaps and uncertainties it is possible that future data collection efforts or analysis may identify other [hazardous air pollutants] of potential concern.”

It is unclear at this point whether other hazardous air pollutants will be regulated on the same timetable as mercury, although EPA has stated that the Agency “must propose regulations to control mercury emissions - and any other air toxics the Agency deems necessary - from coal- and oil-fired power plants by December 15, 2003.”¹⁹

It is difficult to estimate exactly how much any individual will be exposed to specific toxic chemical power plant emissions and what any one person’s health effects from power plant toxic chemical emissions might be. The Edison Electric Institute (EEI), a group representing the electric power industry, has claimed that potential health effects from exposure to power plant emissions are negligible.

EEI’s statements were based on a 1998 EPA study of hazardous air pollutant emissions from power plants.²⁰ While EPA has firmed up some of its previous conclusions, the Agency then determined that some pollutants from power plants are a public health concern that require further study, notably mercury, dioxins, arsenic and nickel. The 1998 study concluded that the high levels of acid gas emissions from power plants do not pose a public health risk, given the Agency’s severely limiting assumptions made in modeling power plant acid gas emissions (and failure

¹⁹ EPA Fact Sheet, December 14, 2000. “EPA to Regulate Mercury and Other Air Toxics Emissions from Coal- and Oil-Fired Power Plants.” (<http://www.epa.gov/ttn/atw/combust/utiltox/hgfs1212.html>).

²⁰ U.S. EPA: *Study of Hazardous Air Pollutant Emissions from Electric Utility Steam Generating Units –Final Report to Congress*. Volume 2: Appendices. 453/R-98-004b. February 1998.

to analyze sensitive populations such as children and the elderly).²¹ EPA's December 2000 announcement indicates that the Agency might now consider regulating power plant acid gas emissions.

The fact is that individual electric power plants release huge quantities of extremely hazardous substances, and also create other types of pollution contributing to public health problems:

- Acid aerosol emissions are corrosive and can cause acute respiratory problems, and aggravate asthma and emphysema. In addition, there is emerging evidence that breathing small concentrations of acid aerosols over time inhibits childhood lung development.²² Furthermore, the fact that acid aerosol emissions from other industries are regulated and controlled demonstrates the recognized necessity of minimizing the health risks associated with their release.
- Several substances released by power plants are also neurotoxins that damage the nervous system, such as manganese compounds and n-hexane, and reproductive and developmental toxins, such as toluene and lead compounds.
- In addition to health effects for individual chemicals, power plant aerosol and metal emissions also contribute to secondary particulate pollution.²³ Emissions of acids and metals coalesce into small droplets and particles that are of particular concern for public health. As many as 30,000 people per year are estimated to die because of exposure to power plant fine particle pollution.²⁴

Where do the chemicals released by power plants come from?

Impurities present in coal and fuel oil are released to the environment when these fuels are burned by power plants. Although coal is mostly carbon, it also contains a small percentage by weight of sulfur compounds, compounds containing chlorine and fluorine, and various metals. While some coal is "cleaner" in that it has fewer impurities, all coal and fuel oil contain some impurities that create a variety of

²¹ While falling short of implicating average emissions of acid gases, the 1998 EPA study did point out that hydrochloric acid emissions have detrimental environmental effects. They significantly enhance the acidity of cloud water and thus can indirectly affect acid rain (by interacting with SO₂ in the atmosphere). It also contributes to the formation of fine particles. According to EPA, hydrochloric acid in the atmosphere can affect the atmospheric chemistry of mercury, which may affect how long mercury remains in the atmosphere before being deposited to earth.

chemical substances when the fuel is burned. These substances end up either as air pollutants or are present in the ash left over after fuel combustion. They are also present in soot captured from the exhaust streams of smokestacks equipped with electrostatic precipitators, scrubbers, or baghouses.

How do legal loopholes and special exemptions affect toxic emissions from power plants?

The huge amount of toxic air pollution from power plants is at least in part the result of special pollution exemptions for the electric industry that currently exist in the Clean Air Act. They also enjoy an exemption under the Resource Conservation and Recovery Act (RCRA) that allows them to dispose of over 100 million tons of toxic combustion waste annually with virtually no restrictions. While ending these special exemptions for power plants will not, by itself, resolve the massive toxic pollution from electricity generation, it is an important part of the solution. In particular, acid aerosols and toxic metals would be reduced by ending special exemptions for power plants.

➤ Acid aerosol air pollution will be reduced by closing the Clean Air Act “grandfather” loophole

Because of a “grandfather” loophole under the Clean Air Act, the vast majority of coal- and oil-fired power plants fail to meet modern pollution standards for sulfur dioxide (SO₂). Grandfathered power plants emit SO₂ at rates up to 10 times that of modern coal plants. Power plants exempted from having SO₂ emission controls under the “grandfather” loophole in Clean Air Act also have higher emissions of acid aerosols than plants that have control systems. ***The average coal-fired power plant with complete SO₂ controls releases 95% less hydrochloric and hydrofluoric acid aerosols per unit of electricity generated than is released by power plants without SO₂ controls, and about 40% less sulfuric acid.***²⁵ Removing the special favoritism conferred by the grandfathering provision in the Clean Air Act would result in substantial reductions in acid aerosol emissions.

If EPA decides to regulate acid aerosol emissions under the rulemaking for hazardous air pollutants, installing SO₂ controls will be a logical way for power plants to comply with the regulation. These controls will also substantially reduce SO₂ emissions, decreasing acid rain, regional haze, and a major source of particulate pollution.

²⁵ Because a large number of power plants burn low sulfur coal, the average percent reduction in emissions of sulfuric acid is lower than for the other acids. For plants burning high sulfur coal, the reduction can be as much as 95 percent from controls, as it is for hydrochloric and hydrofluoric acid. See *Toxic Power: What the Toxics Release Inventory Tells Us about Power Plant Pollution*, (Appendix 2). National Environmental Trust and Clear the Air, August 2000. Available at <http://www.cleartheair.org>.

➤ Toxic metal air pollution will be reduced by closing the Clean Air Act utility air toxics special exemption

Electric utilities have avoided regulation of their toxic pollution due to an exemption granted under the 1990 Clean Air Act.²⁶ At that time, Congress was persuaded that not enough was known about toxics emitted by power plants to justify national regulations. No other major industry was given this exemption.

Mercury is one example of a toxic metal emitted by power plants that has been reduced through the use of controls by other industrial emitters of mercury, and EPA is now beginning the process of developing a mercury emissions standard for power plants. It is uncertain if the Agency will also require controls for other metals, but control technology exists for them. Other toxic metals can be captured to levels exceeding 95 percent and as high as the 99.9 percent by more efficient particulate controls.²⁷

➤ Toxic waste contamination of land and water would be reduced by closing the RCRA combustion waste special exemption

Combustion waste is the solid and liquid waste left over from burning coal and oil to make electricity — ash, sludge, boiler slag, mixed together with a dozen or so smaller volume wastes.²⁸ Every year, over 100 million tons of these wastes are produced at approximately 600 coal and oil-fired power plants. Seventy-six million tons are primarily disposed of at the power plant site in unlined and unmonitored wastewater lagoons, landfills and mines.²⁹

²⁶ Clean Air Act, 42 U.S.C. Sec. 7412(n). Congress ordered EPA to prepare utility air toxics report, and to make a determination on whether to regulate utilities for their toxic emissions. When EPA finally released its utility air toxics study in February 1998, EPA asserted that it did not have enough information to make a positive regulatory determination. At that time, EPA negotiated an extension to December 15, 2000 for making its final determination. Unless EPA determines that utility air toxics should be regulated, power plants will continue to emit far greater quantities of toxic metals and other compounds than industries that are forced to control their toxic emissions.

²⁷ Brown, T.D.; D.N. Smith, R.A. Hargis, Jr., W.J. O'Dowd. *Mercury Measurement and its Control: What we Know, Have Learned and Need to Further Investigate*. J. Air and Waste Management Assoc., June 1999, pp. 1-97.

²⁸ The total amount and potential toxicity of such wastes could increase once controls for air toxics such as mercury, metals, and acid gases are installed, since these controls remove the metals from the air stream as solid or liquid waste.

²⁹ For more details on the hazards of toxic combustion waste, see "Laid to Waste: The Dirty Secret of Combustion Waste From America's Power Plants," (March 2000), available on-line at: <http://www.cleanair.net/Resources/laidtowaste.htm>

These wastes are highly toxic. They contain concentrated levels of contaminants like arsenic, mercury, chromium and cadmium that can damage the nervous systems and other organs, especially in children. Analyses performed for EPA show that some of these pollutants would eventually migrate and contaminate nearby groundwater. Incredibly, disposal of these toxic wastes is subject to no federal requirements whatsoever. In May 2000 EPA issued a regulatory determination for coal combustion waste exempting these wastes from hazardous waste disposal requirements and instead stated its intention to develop state guidelines.

Contamination of land and groundwater by toxic coal and oil combustion waste could be significantly reduced if EPA were to designate these wastes as “hazardous” under RCRA. Coal and oil power plant combustion wastes should require federal regulatory oversight because of the toxicity of their components, the demonstrated and documented danger they pose to public health and the environment. State rules are inadequate to control or mitigate these risks and dangers. The effect of a federal designation of these wastes as hazardous would be significantly tighter controls on disposal of these wastes in landfills and lagoons with modern environmental controls such as liners, groundwater monitoring and leachate collection systems.

What other measures would reduce toxic pollution from power plants?

Even if all existing legal loopholes are closed, there will continue to be massive toxic emissions from power plants. Impurities present in coal and fuel oil, including sulfur compounds, compounds containing chlorine and fluorine, and various metals, will continue to be a source of massive toxic releases so long as these fuels are burned to produce electricity.

Burning cleaner fuels with fewer impurities – such as natural gas – will help lower power plant toxic emissions. In addition, improving energy efficiency and increasing the amount of electricity generated from renewable sources such as biomass, solar, wind and geothermal will further reduce the overall toxic releases from the electric industry.

A national market-based **renewable energy portfolio standard (RPS)** that ensures growth in the percentage of electricity generated from renewable sources including biomass, geothermal, solar and wind energy will help achieve this goal. The RPS requires that each electricity producer offer a set amount of renewable energy, either by acquiring renewable generating capacity or by buying surplus renewable capacity from others.

Finally, reducing overall demand for coal- and oil-generated electricity through energy efficiency measures will also reduce toxic emissions from the power industry. This goal can be achieved by making investments in **energy efficiency** through the establishment of a **nationwide public benefits trust fund**. Investment in the trust fund is accomplished by a uniform charge for transmitting electricity over the existing utility grid.

State TRI Data on Electric Power Plants

How do power plant emissions compare among states?

Table 8 compares electric utility emissions in each state for 2000 TRI air emissions, releases to land and water, and production-related waste. **Ohio** ranked highest for air emissions, followed by **North Carolina, Pennsylvania, West Virginia, and Florida**.

Table 9 compares mercury emissions from electric utilities by state. **Texas** had the highest electric utility mercury air emissions, followed by **Ohio, Pennsylvania, Indiana, and West Virginia**.

Table 10 lists electric utility dioxin emissions by state. **Virginia** ranked highest in 2000, followed by **Florida, Wisconsin, North Carolina, and Pennsylvania**.

Table 11 is a state-by-state listing of all power plants included in the 1998 TRI data. It contains information on reported toxic air emissions, total toxic releases, and production-related waste. **Table 12** is a plant-by-plant listing of data for mercury, and **Table 13** contains plant-by-plant data for dioxin.

Data and Methodology

TRI Data

Data in this report come from the 2000 Toxics Release Inventory database. Facilities designated as electric utilities reported SIC code 4911, 4931, or 4939 as their primary SIC code. In most cases, no other SIC code was reported, although some facilities designated as electric utilities may have other subsidiary operations on site.

New Data for 2000 – New Substances and Lowered Reported Thresholds

The 2000 Toxics Release Inventory data contain new substances, all persistent bioaccumulative toxic (PBT) chemicals. These substances persist in the environment for at least two months without degrading, and concentrate in body tissue. The impact of persistence and bioaccumulation is to increase potential exposure. The new substances reported for 2000 include dioxin and dioxin-like compounds.

All substances designated as PBTs by EPA, both the new substances and substances already on the TRI reporting list (such as mercury and mercury compounds) were also assigned lower reporting thresholds. This means that the 2000 data contain information not previously reported, even though these facilities may have submitted other TRI data in the past.

The TRI Reporting Threshold – Old and New

Facilities report to TRI based on total annual throughput, not on the amount released to the environment. Throughput is defined as the amount of a chemical brought on site plus the amount produced on site during the year, plus the difference in inventory at the beginning and end of the year. It is essentially the amount of a chemical that passes through the facility on an annual basis. Even if a facility has zero releases to the environment, it still must submit a TRI form for each substance meeting the throughput threshold. On the other hand, even if all of a facility's throughput is released to the environment, the facility will not have to report to TRI if the throughput does not meet the threshold.

Originally, the TRI throughput threshold was 25,000 pounds for chemicals manufactured or processed on site -- including some impurities in raw materials, such as mercury contained in coal burned by electric power plants -- and 10,000 for substances "otherwise used" such as solvents and catalysts.¹ Virtually no electric power plants had 25,000 pounds of throughput of mercury, even though most of the mercury in coal burned at power plants ends up released to the

¹ Although mercury is present as an impurity in coal, EPA determined that electric utilities would have to report mercury emissions because various new mercury compounds are formed during the coal combustion process.

environment, so very little data on mercury emissions from power plants was available from TRI.

For the 2000 reporting year, thresholds for substances designated as PBTs were lowered to 10 or 100 pounds, depending on the substances' chemical properties. The threshold for mercury and mercury compounds was set at 10 pounds, meaning that nearly every coal-fired electric power plant reporting to TRI for 2000 reported its mercury emissions. The threshold for dioxin and dioxin-like compounds was set at 0.1 grams, reflecting the extremely small amounts of these substances generated by facilities.

Mercury and Mercury Compounds

As with some other metals, facilities report to TRI separately for elemental mercury and compounds that contain mercury. Total throughput for compounds containing mercury are added to compare against the 10 pound reporting threshold for the "mercury compounds" category, but only the weight of the mercury is included, not the other elements in the compounds. Although elemental mercury and the different mercury compounds may have different chemical and toxicological properties, most tables in this report contain summed data for mercury and mercury compounds together for comparison purposes.

Dioxin and Dioxin-Like Compounds

Unlike metals and metal compounds, dioxin and dioxin-like compounds are included in a single TRI substance category, meaning that the total throughput of these compounds are added together and compared against the 0.1 gram threshold (as opposed to one calculation for dioxin and another for dioxin-like compounds). This approach yields a single number, but that number is difficult to interpret, because one dioxin-like compound can be radically different from another in terms of toxicity. Typically, all dioxin-like compounds are assigned a toxicity weighting factor that indicate each compounds' potency compared to dioxin. That weighting factor is then multiplied by the weight of each compound to give its equivalent toxicity, and the equivalent toxicities of the compounds are added together to give a total "weight" of dioxin based on toxicity. EPA chose not to take this approach in reporting on dioxin-like compounds for many reasons, among them: (1) toxicity weighting factors can change based on new information, and (2) identifying each dioxin-like compound could be time-consuming and costly for facilities.

TRI Releases and Production-Related Waste

Facilities report their air emissions, surface water discharges, releases to land, and amounts of waste injected into on-site deep wells. These quantities were aggregated into total releases as used in this report. Air emissions are the total of stack air emissions and fugitive air emissions, which are reported separately.

Facilities also report amounts of waste managed on site by recycling, burning for energy recovery, and treatment, as well as amounts of waste shipped off site for recycling, energy recovery, treatment, or disposal. These quantities are summed with total releases to calculate production-related waste, which represents amounts of chemicals used on site that do not end up as product. Electric utilities reported some on-site treatment of waste, such as SO₂ controls, but the vast majority of production-related waste from electric power plants ends up as releases.

How Power Plants Estimate Their Emissions

Facilities reporting to TRI are not required to measure their emissions, but to use the best available information. If measurement data are available, facilities will use them to report to TRI.² Facilities measure some of their emissions because of permitting requirements under other environmental statutes, such as the Clean Air Act or Clean Water Act. However, since electric utilities do not have permits for toxic chemical releases, they generally don't measure emissions. Only nine percent of power plant toxic chemical air emissions reported to TRI were measured in 2000.

The vast majority of electric utility toxic chemical releases are estimated by emission factors. An emission factor is essentially a multiplier used with known variables such as fuel consumption or amount of electricity generated. These variables combine to yield emission estimates for various chemicals. Some emission factors can be extremely accurate. For instance, if a facility monitors the amount of various impurities in coal burned, these data can be used to develop emission factors that paint an accurate picture of the quantity of those impurities emitted to the air.

However, there is no requirement for facilities to develop and use such individualized emission factors, and they are just as likely to use national averages as emission factors for impurities in coal. Sixty-six percent of 2000 toxic chemical air emissions from power plants were estimated by emission factors, as compared to 33 percent for non-utility toxic air emissions.

Even if two plants have similar operations, they can report huge differences in releases depending on the emission factors they use. Although TRI requires plants to report that they used emission factors to estimate a given release quantity, they are not required to report which emission factors they used. And since such a large percentage of power plant releases are estimated by emission factors, it is difficult to compare any two power plants to one another. For this

² "Measurement" does not necessarily mean continuous or even frequent measurement. A facility can take a few measurements during the year and extrapolate for the entire year as long as the facility representatives believe that these data are representative of the year's operations. Obviously, this is not always the case.

reason, this report does not rank emissions from individual plants, either nationally or within states.

Parent Company Aggregations

Facilities report the name of their parent companies to TRI. This report uses the parent companies identified by facilities in the TRI database, with no update of parent companies for mergers and acquisitions after December 31, 2000. Facilities may in fact report a subsidiary parent instead of the ultimate parent, so the totals for parent companies may not reflect actual parent company emissions.

Table 1: Toxic Chemical Releases by Industry, 2000 TRI Data*

Rank for Air Emissions	Industry	Total Air Emissions (pounds)	Surface Water Discharges and Releases to Land (pounds)	Total Releases (pounds)	Production-related Waste (pounds)	Number of Facilities Reporting

**Note: This analysis includes one chemical facility that reported the greatest dioxin air emissions in the U.S. If this facility is excluded, electric utilities would be the largest source of air emissions of dioxin and dioxin-like compounds.

Table 7: Electric Utility Emissions of Dioxin and Dioxin-Like Compounds by Parent Company, 2000 TRI Data
